

Assignment #7

Scrum - Scrum is a known agile methodology that is typically used for managing complex projects. Although the main use for scrum was suppose to be for software development, it's framework can be adapted to any part/scope of product development. When product development requires rapid adaptation to change, Scrum is a good fit. Scrum is also a good fit when short development cycles are needed.

Scrum roles - It's design is made for 10 team members. It includes a product owner, development team, and scrum master. The product owner is in control of the vision of the product. The product owner is responsible for setting the priorities of the requirements and control over the budget. The development team is responsible for completing the work. It decides their tasks independently, deciding which requirements or User stories they can complete in one sprint. Scrum master is essentially somebody in the group that is in charge of observing the team, making sure the everything goes according to plan. Scrum master doesn't interfere with decisions of the team regarding the development of said product. They are merely advisors, only interfering when somebody of the team is breaking the rules.
